

1 Description

2

3 Method and device for voltage measurement

4

5 The invention relates to a method for measuring the voltage
6 at a point in a power distribution network by means of a
7 measuring circuit, which has a voltage sensor, which is
8 coupled to a current-carrying conductor of the network, and
9 a further-processing arrangement, which is connected to the
10 voltage sensor, and outputs a measured voltage value as the
11 output signal at its output, and to an apparatus for
12 carrying out this method.

13

14 In power distribution networks, preferably in the voltage
15 range of 6-20 kV, at present devices are still predominantly
16 used for protection and control purposes which represent
17 directionally independent overcurrent protection. This is
18 sufficient in networks having a central supply and in which
19 the current direction is predetermined. In the case of a
20 decentralized supply, however, it is also necessary, for the
21 response of protective devices, for the direction of a
22 current to also be detected, in addition to the level of the
23 current. This can be determined by additional voltage
24 measurements in the network. For this purpose, inductive
25 voltage transformers are generally used today as the voltage
26 sensors. They make it possible to measure the voltage
27 accurately, but represent a considerable cost factor, in
28 particular if they are installed retrospectively in existing
29 networks.

30

31 The German laid-open specification DE 23 25 449 A1 describes
32 the use of a capacitive voltage transformer as a voltage
33 sensor for the purpose of measuring the voltage in high-
34 voltage switchgear assemblies, said voltage transformer
35 being formed from a current-carrying conductor of the high-
36 voltage network and an electrode embedded in a post
37 insulator of the conductor. Such capacitive voltage
38 transformers are generally used today, however, merely for

1 establishing the presence of a voltage having a specific
2 minimum level on a line of a power distribution network the
3 displacement current of a high-voltage coupling capacitor,
4 since the measurement result obtained is sometimes
5 relatively inaccurate, with the result that it can only be
6 used to establish the presence of the voltage but not to
7 determine its precise value.

8
9 The object of the present invention is to specify a method
10 and an apparatus of the abovementioned type, by means of
11 which accurate voltage measurement can be carried out
12 irrespective of the type of voltage sensor.

13
14 In terms of the method, this object is achieved according to
15 the invention by the fact that, in a method of the mentioned
16 type, the output signal from the measuring circuit is
17 corrected so as to achieve a correct measured value by means
18 of a correction element having a transfer function which is
19 inverse to the transfer function of the measuring circuit.
20 As a result of the fact that the output signal from the
21 measuring circuit is corrected so as to achieve a correct
22 measured value by means of a correction element having a
23 transfer function which is inverse to the transfer function
24 of the measuring circuit, it is possible, using
25 comparatively simple means, for sufficiently accurate
26 voltage measurement to be carried out irrespective of the
27 type of voltage sensor.

28
29 The method according to the invention can advantageously
30 provide for a capacitor device to be used as the voltage
31 sensor of the measuring circuit. The use of a capacitor
32 device - i.e. a capacitive voltage transformer - as the
33 voltage sensor represents a comparatively cost-effective
34 possibility for voltage measurement.

35
36 In this context, it is also regarded as advantageous if a
37 coupling capacitor, formed from the current-carrying
38 conductor of the network and an electrode which is

1 DC-isolated from said current-carrying conductor, is used as
2 the capacitor device. Such capacitor devices have a
3 comparatively simple design; in addition, capacitor devices
4 of this type are already often provided, for example, in
5 high-voltage bushings of switchgear cells.

6
7 As an alternative, however, it is also advantageously
8 possible to provide for an inductive voltage transformer,
9 which is connected on the primary side to the
10 current-carrying conductor, to be used as the voltage
11 sensor. This is regarded as being particularly advantageous
12 because such an inductive voltage transformer generally
13 makes very accurate voltage measurement possible. Since,
14 however, the measuring circuit can also have a transfer
15 function which slightly falsifies the measured voltage value
16 when an inductive voltage transformer is used, even more
17 accurate measured voltage values can be achieved in this
18 case too when using the correction by means of the
19 correction element in accordance with the method according
20 to the invention.

21
22 In this case, however, it is also regarded as advantageous
23 if a correction element is used which can optionally be
24 bypassed via a switch. In this manner, the correction
25 element can easily be bypassed if the measured voltage
26 values achieved using the inductive voltage transformer are
27 sufficiently accurate; in such a case no correction of the
28 measured voltage values therefore takes place.

29
30 Depending on whether the output signal from the measuring
31 circuit is analog or digital, an analog or digital filter
32 having a transfer function which is inverse to the transfer
33 function of the measuring circuit can be used as the
34 correction element. The analog filter expediently simulates
35 a transfer function having a PID characteristic.

36
37 When using a digital filter, a temporally discrete transfer
38 function is suitable as the inverse transfer function. This

1 can be generated in a manner known per se by means of a
2 bilinear transformation.

3
4 In this context, it is also regarded as advantageous if, in
5 the case of the digital filter, the coefficients of the
6 temporally discrete transfer function can be altered. In
7 this case, the transfer function of the correction element
8 can be matched in a particularly simple manner to transfer
9 functions of the measuring circuit brought about by
10 different voltage sensors.

11
12 One further advantageous development of the method according
13 to the invention also provides for a further-processing
14 arrangement to be used which has a DC isolating element in
15 its input region. The further-processing arrangement and the
16 correction element can thus be DC-isolated from the
17 high-voltage side without any problems.

18
19 In terms of the apparatus, the object on which the invention
20 is based is achieved by a measuring apparatus for measuring
21 the voltage at a point in a power distribution network by
22 means of a measuring circuit, which has a voltage sensor,
23 which is coupled to a current-carrying conductor of the
24 network, and a further-processing arrangement, which is
25 connected to the voltage sensor, and outputs a measured
26 voltage value as the output signal at its output, a
27 correction element being connected to the measuring circuit
28 on the output side in accordance with the invention so as to
29 achieve a correct measured value from the output signal from
30 the measuring circuit, said correction element having a
31 transfer function which is inverse to the transfer function
32 of the measuring circuit. Owing to the use of a correction
33 element having a transfer function which is inverse to the
34 transfer function of the measuring circuit, it is possible
35 to achieve accurate measured voltage values with such a
36 measuring apparatus using any desired measuring sensors.

37

1 For reasons of cost, provision can advantageously be made
2 for the voltage sensor to be a capacitor device. In
3 accordance with one preferred embodiment, such a capacitor
4 device may also be a coupling capacitor formed from the
5 current-carrying conductor of the network and an electrode
6 which is DC-isolated from said current-carrying conductor.
7 An electrode having this design may preferably be a
8 so-called ring electrode.

9
10 As an alternative, however, provision may also be made for
11 the voltage sensor to be an inductive voltage transformer,
12 which is connected on the primary side to the
13 current-carrying conductor.

14
15 Since such an inductive voltage transformer often already
16 produces measured voltage values of a very high quality, in
17 this context provision may also be made for it to be
18 possible for the correction element to be optionally
19 bypassed via a switch.

20
21 However, even in the case of an inductive voltage
22 transformer, the quality of the measured voltage values can
23 often be increased further still by the use, according to
24 the invention, of a correction element having an inverse
25 transfer function, with the result that it is also
26 worthwhile in this case to use the correction element, which
27 in this case is therefore not bypassed.

28
29 In other words, a measuring apparatus according to the
30 invention has, for example, an input terminal for the
31 optional connection to any desired voltage sensors, for
32 example to the electrode of the coupling capacitor or to the
33 secondary winding of an inductive voltage transformer, which
34 is connected on the primary side to the current-carrying
35 conductor. As a result, it is in this case possible to
36 connect the measuring apparatus to the corresponding voltage
37 sensor irrespective of whether a coupling capacitor or an
38 inductive voltage transformer has already been installed at

1 the measurement point in the network. The measuring
2 apparatus is then provided with a switch for optionally
3 switching the correction element which simulates the inverse
4 transfer function on or off in order to switch the
5 correction element on in the event of a connection to the
6 coupling capacitor and to switch the correction element off,
7 if required, in the event of a connection to the voltage
8 transformer. Even in the case of the inductive voltage
9 transformer, in this case the correction element could
10 remain switched on, in which case the inverse transfer
11 function of said correction element would have to be
12 correspondingly altered. It would be possible for this to be
13 carried out in a simple manner, in particular in the case of
14 a digital filter having a temporally discrete transfer
15 function as the correction element, by adjusting the
16 coefficients.

17
18 Depending on whether the output signal from the measuring
19 circuit is an analog or a digital output signal, an analog
20 filter having a PID characteristic or a digital filter can
21 correspondingly be used.

22
23 One advantageous development of the measuring apparatus
24 according to the invention provides for the
25 further-processing arrangement to have a DC isolating
26 element in its input region. It is thus possible to
27 DC-isolate the high-voltage part of the measuring apparatus
28 from the low-voltage part in a simple manner. The DC
29 isolating element can preferably be an inductive current
30 transformer.

31
32 In accordance with one further advantageous development of
33 the measuring apparatus according to the invention, the
34 voltage sensor is connected on the output side to a series
35 circuit comprising a resistor having a high resistance value
36 and the primary winding of the inductive current
37 transformer. The input voltage of the further-processing
38 arrangement is converted to a comparatively low current via

1 the resistor having a high resistance value such that the
2 inductive current transformer can be designed to be
3 comparatively small and thus inexpensive.

4
5 One further advantageous development of the measuring
6 apparatus according to the invention also provides for the
7 secondary winding of the current transformer to be loaded by
8 a negative feedback operational amplifier with an internal
9 resistance of 0 ohm. In turn, a current/voltage conversion
10 takes place using the operational amplifier, in which case
11 the range of the level of the resulting voltage can be
12 adjusted by the negative feedback of the operational
13 amplifier, for example via a resistor arranged in the
14 negative feedback path.

15
16 In addition, one advantageous embodiment of the measuring
17 apparatus according to the invention is regarded as the fact
18 that the measuring circuit has an analog-to-digital
19 converter on the output side in order to generate digital
20 output signals from the measurement arrangement.

21
22 The invention will be explained in more detail below with
23 reference to an exemplary embodiment illustrated in the
24 figure. The figure shows the circuit diagram of a measuring
25 apparatus MV for voltage measurement using a digital filter
26 as the correction element KG in order to correct the
27 measured voltage values.

28
29 A current conductor 1 of a power distribution network forms
30 an electrode of a capacitive voltage transformer as the
31 voltage sensor SG in the form of a high-voltage coupling
32 capacitor 2. The other electrode of the coupling capacitor
33 2, which is preferably passed around the current conductor 1
34 in annular fashion such that it is DC-isolated from said
35 current conductor 1, is connected to an input terminal 3 of
36 a further-processing arrangement WA of the measuring
37 apparatus MV. In a similar manner, other forms of capacitive
38 voltage transformer are also possible as the voltage sensor

1 SG, however. As illustrated in the figure, the capacitive
2 voltage transformer may optionally be a capacitive divider,
3 whose low-voltage capacitor is represented by dashed lines
4 in the figure. An embodiment in the form of a capacitive
5 divider is not absolutely necessary, however. Instead, as is
6 indicated by the further dashed line, the secondary winding
7 of an inductive voltage transformer 4, which is connected on
8 the primary side to the current conductor 1, can also be
9 connected to the input terminal 3 of the further-processing
10 arrangement WA. As is indicated in the figure by the curved
11 bracket, the voltage sensor SG and the further-processing
12 arrangement WA together form a so-called measuring circuit
13 MS.

14
15 The text which follows will consider the case in which the
16 coupling capacitor 2 as the voltage sensor SG is connected
17 to the input terminal 3 of the further-processing
18 arrangement WA. A series resistor 5 (R_v), which generally
19 has a high resistance value and is arranged downstream of
20 the input terminal 3, carries out a voltage/current
21 conversion of the voltage, which has been tapped off
22 capacitively at the electrode, which is DC-isolated from the
23 current conductor 1, of the coupling capacitor 2, to a
24 displacement current. In addition, the series resistor 5
25 forms, with the capacitance of the coupling capacitor 2, a
26 high-pass filter and therefore improves the input-side EMC
27 (electromagnetic compatibility) performance of the measuring
28 apparatus MV.

29
30 A DC isolating element, which is connected on the primary
31 side in series with the series resistor 5 and is in the form
32 of an inductive current transformer 6, on the one hand
33 serves the purpose of potential isolation and, on the other
34 hand, serves the purpose of reducing the coupling
35 capacitance with respect to the high-voltage conductor and
36 thus brings about further EMC shielding. Owing to the
37 displacement current which is low as a result of the

1 dimensions of the series resistor 5, the inductive current
2 transformer 6 can be designed to be relatively small.

3
4 An operational amplifier 7 having a feedback resistor 8 (R_m)
5 is connected to the secondary side of the inductive current
6 transformer 6. The operational amplifier 7 acts as an active
7 load for the inductive current transformer 6 with an
8 internal resistance of 0 ohm. At the same time, the
9 operational amplifier 7 takes on the function of
10 current/voltage conversion and converts the current produced
11 by the inductive current transformer 6 to a voltage. The
12 ratio between the output voltage and the input current of
13 the operational amplifier 7 is determined by the value R_m
14 for the feedback resistor 8. This value can be switched over
15 by means of a link or an analog switch, as indicated in the
16 figure, in order to be able to match the driving of the
17 current transformer 6, which driving is dependent on the
18 coupling capacitor 2 or the voltage transformer 3, to the
19 measurement range of an analog-to-digital converter 9
20 downstream of the operational amplifier 7.

21
22 Said analog-to-digital converter 9 converts its input
23 voltage to a digital sample sequence.

24
25 If the input terminal 3 of the further-processing
26 arrangement WA is connected to the inductive voltage
27 transformer 4, the transfer performance of the measuring
28 circuit MS formed from the voltage sensor SG (i.e. in this
29 case the inductive voltage transformer 4) and the
30 further-processing arrangement WA is independent of the
31 frequency in the relevant frequency range (50 or 60 Hz).

32
33 In contrast, in the event of a connection to the coupling
34 capacitor 2, the following transfer function for the
35 measuring circuit MS to the analog-to-digital converter 9
36 results:

37
38

$$\frac{U_A}{U_{Prim}} = \frac{j\omega C_D \cdot R_m}{1 + j\omega C_D \cdot R_v}$$

where U_A is the voltage at the output of the operational amplifier 7, U_{Prim} is the voltage of the current conductor 1, and C_D is the capacitance of the coupling capacitor 2. If the value for U_A resulting using this transfer function is left unchanged, a measured voltage value is obtained which is completely unsuitable for accurate voltage measurement. The transfer function of the entire measuring apparatus MV (comprising the voltage sensor SG, the further-processing arrangement WA and the correction element KG) therefore needs to be corrected by a downstream correction element KG by means of a transfer function which is inverse to the transfer function of the measuring circuit MS. This correcting inverse transfer function of the correction element KG should be formed in accordance with the following equation:

$$G_{corr} = \frac{1 + j\omega C_D \cdot R_v}{1 + j\omega T_K}$$

The resultant transfer function of the entire measuring apparatus MV in turn represents a high-pass filter, but with a new cut-off frequency $1/(2 \cdot \pi \cdot T_K)$. The time constant T_K can in this case be selected such that the cut-off frequency is below the frequency range to be detected for the measured voltage value, with the result that the transfer function of the entire measuring apparatus MV is linear in this frequency range. It is particularly advantageous if T_K is equal to the time constant of the current transformer used for detecting the current signals, which are likewise measured at the same time as the voltage signal.

If, as shown in the figure, a digital filter 10 is used to correct the transfer function of the measuring circuit MS, the correcting transfer function G_{corr} can previously be transformed into a temporally discrete transfer function $G(z^-)$

1) . This takes place with the aid of the bilinear transformation

$$e^{-j\omega T_A} = \frac{2}{T_A} \cdot \frac{z+1}{z-1}.$$

The right-hand side of this equation is the series expansion, terminated after the first element, of the function $e^{-j\omega \cdot T}$. This gives:

$$G(z^{-1}) = \frac{a_1 z^{-1} + a_0}{1 + b_1 z^{-1}},$$

where z^{-1} is the delay of a sampled value by a sampling interval; a_0 , a_1 and b_1 are coefficients of the temporally discrete transfer function. This temporally discrete transfer function $G(z^{-1})$ is implemented by the digital filter 10 illustrated in the figure. This in turn has a final amplification at the frequency 0, with the result that the numerical stability of the apparatus is ensured even in the case of an offset of the analog-to-digital converter 9.

A switch 11 is used to connect the output of the analog-to-digital converter 9 to the measured value output 12 of the measuring apparatus MV either directly or via the digital filter 10. The direct connection can be selected if the inductive voltage transformer 4 as the voltage sensor SG is connected to the input terminal 3 of the further-processing arrangement WA, and the connection via the digital filter 10 is selected if the coupling capacitor 2 as the voltage sensor SG is connected to the input terminal 3. The switch 11 could, however, also be dispensed with, with the result that, in both cases, the digital filter 10 is included since an improvement in the quality of the measured voltage values can be achieved owing to the shift in the cut-off frequency of the transfer function of the entire measuring apparatus MV even in the case in which the inductive voltage transformer 4 is used. However, the

1 coefficients of the digital filter 10 can in each case be
2 adjusted differently for the connection to the inductive
3 voltage transformer 4, on the one hand, and to the coupling
4 capacitor 2, on the other hand.

5
6 Correspondingly, a measuring apparatus can also be
7 implemented using analog voltage signals, in which case an
8 analog filter would be used in place of the digital filter,
9 and the analog-to-digital converter would be dispensed with.

10
